

Monitoring the Dutch *P. infestans* population for virulence against new R- genes

Marieke Förch, Trudy van den Bosch, Petra van Bekkum,
Bert Evenhuis, Jack Vossen and Geert Kessel

Introduction

- *S. demissum* R-genes R1 – R11 introduced in the past
- New R-genes have / will be introduced to the market:
 - Sarpo mira,
 - Toluca (Blb2)
 - Bionica (Blb2)
 - Fortuna (BASF, Blb1 + Blb2),
....
- More is to come:
 - *S. berthaultii*
 - *S. stoloniferum*
 - *S. chaquense*
 - *S. venturi*
 - *S. edinense*
- A need to monitor for virulence!

Phytophthora

Materials & Methods

- Annual sampling of NL *P. infestans* population:
 - Farmers fields, dumps, volunteers etc.
 - Bait fields at three locations:
 - Resistant (commercial) cultivars
 - R1 – R11 differential set (up to 2008)
 - Advanced breeding lines NL breeders
 - Wild *Solanum* spp.
 - Unprotected by fungicides
 - Sampled weekly, active *P. infestans* removed
 - *P. infestans* isolates individually characterized

Lelystad 2009 Bait field ~ 100 genotypes

Virulence monitoring: Blb1 + Blb2 (stacked)

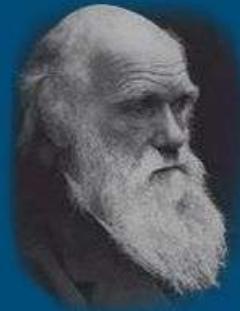

In Conclusion

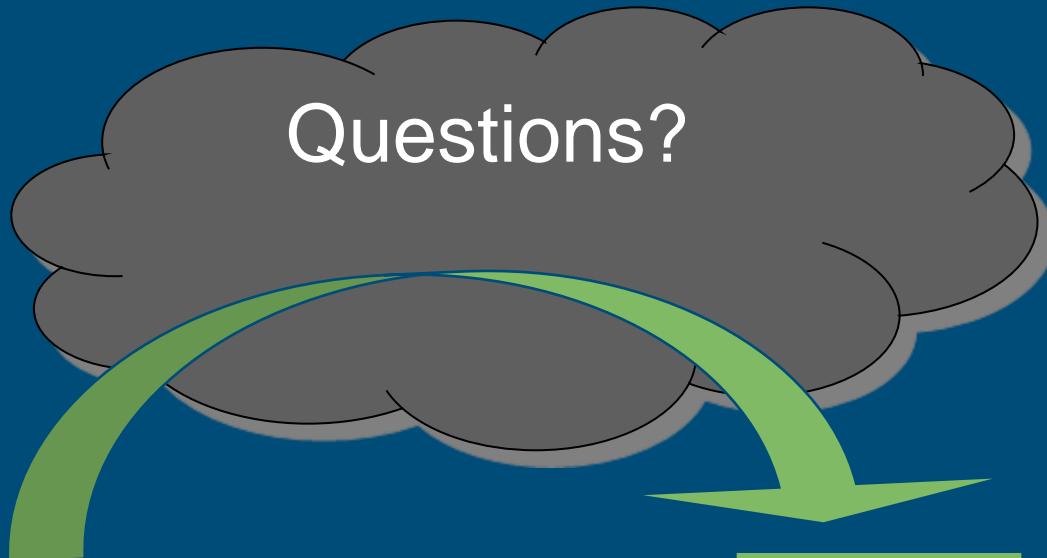

- Phytophthora still adapts
 - Also the new R-genes can be broken:
 - Virulence for all single R-genes tested is found in the detached leaf test although some are rare!
 - Most Solanum genotypes are also infected in bait fields
 - Virululence for stacked Blb1 + Blb2 is found in detached leaf test
 - Two options:
 - Virulence was present in the Pi gene pool
 - On site mutations
 - » Mutations occur on a susceptible host.....
 - » Selection takes place on the resistant host!
 - » 1×10^8 spores/m² leaf → 4×10^{12} spores/ha
- Future growing systems:
 - Resistant cultivars (conventional / GMO)
 - + Low level input of fungicides
 - Prevent large outbreaks
